1 Introduction

▲□▶ ▲□▶ ▲□▶ ▲□▶ = 三 のへぐ

Most of statistical inferences are often associated with limit theorems for random variables or stochastic processes.

1 Introduction

Most of statistical inferences are often associated with limit theorems for random variables or stochastic processes. Weak convergence of stochastic processes is a very important and foundational theory in probability and statistics. Billingsley (1999) gave a systematic classical theory of weak convergence for stochastic processes.

For identifying the limiting process, there are serval methods. Usually, when the limiting process is Guassian process, one can identify the limiting process by proving the convergence of the finite dimensional distributions.

For identifying the limiting process, there are serval methods. Usually, when the limiting process is Guassian process, one can identify the limiting process by proving the convergence of the finite dimensional distributions.

When the finite dimensional distributions of limiting processes are difficult to compute, this method can not be easily used.

For identifying the limiting process, there are serval methods. Usually, when the limiting process is Guassian process, one can identify the limiting process by proving the convergence of the finite dimensional distributions.

When the finite dimensional distributions of limiting processes are difficult to compute, this method can not be easily used. An alternative method is martingale convergence method. This method is based on the Martingale Problem of Semimartingales. When the limiting processes are semimartingales, martingale convergence method is effective.

The idea of martingale convergence method originate in the work of Stroock and Varadhan (Stroock and Varadhan (1969)). In Jacod and Shiryaev (2003), they gave a whole system of this method. When limiting process is a jump-process, their results are very powerful.

The idea of martingale convergence method originate in the work of Stroock and Varadhan (Stroock and Varadhan (1969)). In Jacod and Shiryaev (2003), they gave a whole system of this method. When limiting process is a jump-process, their results are very powerful.

Recently, martingale convergence method is usually used in the study of convergence of processes, such as discretized processes and statistics for high frequency data. (c.f. Jacod (2008), A*i*t-Sahalia and Jacod (2009), Fan and Fan (2011)).

The idea of martingale convergence method originate in the work of Stroock and Varadhan (Stroock and Varadhan (1969)). In Jacod and Shiryaev (2003), they gave a whole system of this method. When limiting process is a jump-process, their results are very powerful.

Recently, martingale convergence method is usually used in the study of convergence of processes, such as discretized processes and statistics for high frequency data. (c.f. Jacod (2008), $A\ddot{i}t$ -Sahalia and Jacod (2009), Fan and Fan (2011)). However, it is rarely used in the contents of time series.

To our knowledge, Ibragimov and Phillips (2008) firstly introduced the martingale convergence method to the study of time series. They studied the weak convergence of various general functionals of partial sums of linear processes. The limiting process is a stochastic integral. Their result was used in the study for unit root theory.

To our knowledge, Ibragimov and Phillips (2008) firstly introduced the martingale convergence method to the study of time series. They studied the weak convergence of various general functionals of partial sums of linear processes. The limiting process is a stochastic integral. Their result was used in the study for unit root theory.

When the limiting processes are jump-processes, their methods may be useless, since they need that the residual in martingale decomposition is neglected, which may not be satisfied in the jump case.

Now, we extend Ibragimov and Phillips's results to two directions. One is about causal processes.

Now, we extend Ibragimov and Phillips's results to two directions. One is about causal processes. Causal processs $\{X_n, n \ge 1\}$ is defined by

$$X_n = g(\cdots, \varepsilon_{n-1}, \varepsilon_n),$$

うして ふゆう ふほう ふほう ふしつ

where $\{\varepsilon_n; n \in Z\}$ is a sequence of i.i.d. r.v.'s with mean zero and g is a measurable function.

Now, we extend Ibragimov and Phillips's results to two directions. One is about causal processes. Causal processs $\{X_n, n \ge 1\}$ is defined by

$$X_n = g(\cdots, \varepsilon_{n-1}, \varepsilon_n),$$

where $\{\varepsilon_n; n \in Z\}$ is a sequence of i.i.d. r.v.'s with mean zero and g is a measurable function. It contains many important stochastic models, such as linear process, ARCH model, threshold AR (TAR) model and so on.

Wiener (1958) conjectured that for every stationary ergodic process $\{X_n, n \ge 1\}$, there exists a function g and i.i.d. $\varepsilon_n, n \ge 1$ such that

$$X_n = \mathfrak{D} g(\cdots, \varepsilon_{n-1}, \varepsilon_n).$$

ション ふゆ くち くち くち くち くち

Wiener (1958) conjectured that for every stationary ergodic process $\{X_n, n \ge 1\}$, there exists a function g and i.i.d. $\varepsilon_n, n \ge 1$ such that

$$X_n = \mathfrak{D} g(\cdots, \varepsilon_{n-1}, \varepsilon_n).$$

We study weak convergence of functional of causal processes. The limiting process is the stochastic integral driven by the Brownian motion. The result extends the results in Ibregimov and Phillips (2008) to causal process, and our assumptions are more wild than theirs.

うして ふゆう ふほう ふほう ふしつ

Wiener (1958) conjectured that for every stationary ergodic process $\{X_n, n \ge 1\}$, there exists a function g and i.i.d. $\varepsilon_n, n \ge 1$ such that

$$X_n = \mathfrak{D} g(\cdots, \varepsilon_{n-1}, \varepsilon_n).$$

We study weak convergence of functional of causal processes. The limiting process is the stochastic integral driven by the Brownian motion. The result extends the results in Ibregimov and Phillips (2008) to causal process, and our assumptions are more wild than theirs.

We extend Ibregimov and Phillips's work to another direction: $\{X_n\}$ is a sequence of heavy-tailed random variables.

We discuss an important class of heavy-tailed random variables. A random variable X, the so-called regularly varying random variables with index $\alpha \in (0, 2)$ if there exists a positive parameter α such that

$$\lim_{x \to \infty} \frac{P(X > cx)}{P(X > x)} = c^{-\alpha}, \quad c > 0.$$

We study weak convergence of functionals of the i.i.d. regularly varying random variables. The limiting process is the stochastic integral driven by α -stable Lévy process.

うして ふゆう ふほう ふほう ふしつ

Usually, people obtain the weak convergence of heavy-tailed random variables by point process method. In this case, the summation functional should be a continuous functional respect to the Skorohod topology , and the limiting process should have a compound Poisson representation.

ション ふゆ マ キャット キャット しょうくしゃ

Usually, people obtain the weak convergence of heavy-tailed random variables by point process method. In this case, the summation functional should be a continuous functional respect to the Skorohod topology , and the limiting process should have a compound Poisson representation.

However, if we want to extend Ibragimov and Phillips's results to the heavy-tailed random variables, the point process method can not be used easily, since the limiting process has jumps.

Because the limiting process has jumps, we have to modify the proof procedure in Ibragimov and Phillips (2008). Our method is not only effective for the jump case but also simpler than that of Ibragimov and Phillips (2008)(only for the continuous case).

うして ふゆう ふほう ふほう ふしつ

We use the martingale approximation procedure, strong approximation of martingale and the martingale convergence method to prove our theorems.

▲□▶ ▲□▶ ★ □▶ ★ □▶ = □ の < ⊙

We use the martingale approximation procedure, strong approximation of martingale and the martingale convergence method to prove our theorems.

Martingale approximation procedure. Let $\{X_n\}$ be a sequence of random variables, $S_n = \sum_{k=1}^n X_k$. We can structure a martingale M_n , If the error $S_n - M_n$ is small enough in some sense, we can consider M_n instead of S_n .

We use the martingale approximation procedure, strong approximation of martingale and the martingale convergence method to prove our theorems.

Martingale approximation procedure. Let $\{X_n\}$ be a sequence of random variables, $S_n = \sum_{k=1}^n X_k$. We can structure a martingale M_n , If the error $S_n - M_n$ is small enough in some sense, we can consider M_n instead of S_n .

Strong approximation of martingale. Let M_n , $n = 1, 2, \dots$, be a sequence of martingales. Under some conditions, we can find a Brownian motion (or Gaussian process) B such that $M_n - B \rightarrow 0$ a.s. with some rate.

Martingale convergence method.

The following theorem makes out that the limiting process for weak convergence of martingale sequence is still a martingale.

Martingale convergence method.

The following theorem makes out that the limiting process for weak convergence of martingale sequence is still a martingale. **Theorem A** (Jacod and Shiryaev (2003)) Let Y^n be a càdlàg process and M^n be a martingale on a same filtered probability space $(\Omega, \mathscr{F}, \mathbb{F} = (\mathscr{F}_t)_{t\geq 1}, P)$. Let M be a càdlàg process defined on the canonical space $(\mathbb{D}([0,1]), \mathscr{D}([0,1]), \mathbf{D})$. Assume that (i) (M^n) is uniformly integrable; (ii) $Y^n \Rightarrow Y$ for some Y with law $\widetilde{P} = \mathscr{L}(Y)$; (iii)

$$M_t^n - M_t \circ (Y^n) \xrightarrow{P} 0, \quad 0 \le t \le 1$$

Then the process $M \circ (Y)$ is a martingale under \tilde{P} .

Let M^n , $n = 1, 2, \dots$, be a sequence of martingales. The predictable characteristic of M^n is a triplet (B_n, C_n, ν_n) . If there exists limit (B, C, ν) , then one can identify the limiting process M by (B, C, ν) .

うして ふゆう ふほう ふほう ふしつ

2 Convergence to Stochastic Integral Driven by Brownian Motion

Recall that $Z \in L^p$ (p > 0) if $||Z||_p = [E(|Z|^p)]^{1/p} < \infty$ and write $||Z|| = ||Z||_2$. To study the asymptotic property of the sums of causal process

$$X_n = g(\cdots, \varepsilon_{n-1}, \varepsilon_n),$$

martingale approximation is an effective method. We list the notations used in the following part:

•
$$\mathscr{F}_k = \sigma(\cdots, \varepsilon_{k-1}, \varepsilon_k).$$

• Projections $P_k Z = E(Z|\mathscr{F}_k) - E(Z|\mathscr{F}_{k-1}), Z \in L^1.$
• $D_k = \sum_{i=k}^{\infty} P_k X_i, M_k = \sum_{i=1}^k D_i.$
 M_k is a martingale, we will use M_k to approximate sum $S_k.$
• $\theta_{n,p} = ||P_0 X_n||_p, \Lambda_{n,p} = \sum_{i=0}^n \theta_{i,p}, \Theta_{m,p} = \sum_{i=m}^{\infty} \theta_{i,p}.$
• B : standard Brownian motion.

◆□▶ ◆昼▶ ◆臣▶ ◆臣▶ ○日 ◆

Assumption 1. $X_0 \in L^q$, $q \ge 4$, and $\Theta_{n,q} = O(n^{-1/4} (\log n)^{-1})$. Assumption 2.

$$\sum_{k=1}^{\infty} ||E(D_k^2|\mathscr{F}_0) - \sigma^2||_2 < \infty,$$

where $\sigma = ||D_k||$. Assumption 3.

$$\sum_{k=0}^{\infty}\sum_{i=1}^{\infty}||E(X_kX_{k+i}|\mathscr{F}_0) - E(X_kX_{k+i}|\mathscr{F}_{-1})||_4 < \infty,$$

and

$$||\sum_{k=0}^{\infty}\sum_{i=1}^{\infty}E(X_kX_{k+i}|\mathscr{F}_0)||_3<\infty.$$

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ ―臣 – のへで

Remark 1 If we consider linear process to replace the causal process, Assumptions $1 \sim 3$ can easily be implied by the conditions in Ibragimov and Phillips (2008).

▲□▶ ▲□▶ ★ □▶ ★ □▶ = □ の < ⊙

Theorem 1 Let $f : \mathbb{R} \to \mathbb{R}$ be a twice continuously differentiable function satisfying $|f'(x)| \leq K(1 + |x|^{\alpha})$ for some positive constants K and α and all $x \in \mathbb{R}$. Suppose that X_t is a causal process satisfying Assumptions 1~3. Then

$$\frac{1}{\sqrt{n}} \sum_{t=2}^{[n\cdot]} f(\frac{1}{\sqrt{n}} \sum_{i=1}^{t-1} X_i) X_t \Rightarrow \lambda \int_0^{\cdot} f'(B(v)) dv + \sigma \int_0^{\cdot} f(B(v)) dB(v),$$
(2.1)
where $\lambda = \sum_{i=1}^{\infty} E Y_i X_i$

ション ふゆ マ キャット キャット しょうくしゃ

where $\lambda = \sum_{j=1}^{\infty} E X_0 X_j$.

Remark 2 When f(x) = 1, Theorem 1 is the classical invariance principle, when f(x) = x, (2.1) is important in the unit root theory.

Remark 2 When f(x) = 1, Theorem 1 is the classical invariance principle, when f(x) = x, (2.1) is important in the unit root theory.

Let

$$Y_n = \alpha Y_{n-1} + X_n,$$

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ ―臣 – のへで

where $\{X_n\}_{n\geq 0}$ is a causal process, and want to estimate α from $\{Y_t\}$.

Let

$$\hat{\alpha} = \frac{\sum_{t=1}^{n} Y_{t-1} Y_{t}}{\sum_{t=1}^{n} Y_{t-1}^{2}}$$

denote the ordinary least squares estimator of α . Let t_{α} be the regression *t*-statistic:

$$t_{\alpha} = \frac{\left(\sum_{t=1}^{n} Y_{t-1}^{2}\right)^{\frac{1}{2}} (\hat{\alpha} - 1)}{\sqrt{\frac{1}{n} \sum_{t=1}^{n} (Y_{t} - \hat{\alpha} Y_{t-1})}}.$$

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ ―臣 – のへで

Using Theorem 1 with f(x) = x, we get the asymptotic distribution of $n(\hat{\alpha} - 1)$ and t_{α} as follows.

Theorem 2 Under Assumptions 1-3, we have

$$n(\hat{\alpha}-1) \xrightarrow{d} \frac{\lambda + \sigma^2 \int_0^1 B(v) dB(v)}{\sigma^2 \int_0^1 B^2(v) dv},$$
(2.1)

$$t_{\alpha} \xrightarrow{d} \frac{\lambda + \sigma^2 \int_0^1 B(v) dB(v)}{(\int_0^1 B^2(v) dv)^{\frac{1}{2}}}.$$

We can construct the confidence interval of α for the unit root testing.

3 Convergence to Stochastic Integral Driven by Lévy α -Stable Process

Let $E = [-\infty, \infty] \setminus \{0\}$ and $M_p(E)$ be the set of Radon measures on E with values in \mathbb{Z}_+ , the set of positive integers.

・ロト ・ 日 ・ モ ・ ト ・ モ ・ うへぐ

3 Convergence to Stochastic Integral Driven by Lévy α -Stable Process

Let $E = [-\infty, \infty] \setminus \{0\}$ and $M_p(E)$ be the set of Radon measures on E with values in \mathbb{Z}_+ , the set of positive integers. For $\mu_n, \mu \in M_p(E)$, we say that μ_n vaguely converge to the measure μ , if

$$\mu_n(f) \to \mu(f)$$

for any $f \in C_K^+$, where C_K^+ is the class of continuous functions with compact support, denoted by $\mu_n \xrightarrow{v} \mu$.

Theorem 3 Let $f : \mathbb{R} \to \mathbb{R}$ be a continuous differentiable function such that

$$|f(x) - f(y)| \le K|x - y|^a$$
(3.1)

for some positive constants K, a and all $x, y \in \mathbb{R}$. Suppose that $\{X_n\}_{n\geq 1}$ is a sequence of i.i.d. random variables. Set

$$X_{n,j} = \frac{X_j}{b_n} - \mathbb{E}(h(\frac{X_j}{b_n}))$$
(3.2)

うして ふゆう ふほう ふほう ふしつ

for some $b_n \to \infty$, where h(x) is a continuous function satisfying h(x) = x in a neighbourhood of 0 and $|h(x)| \le |x| \mathbf{1}_{|x| \le 1}$.

Define ρ by

$$\rho((x, +\infty]) = px^{-\alpha}, \quad \rho([-\infty, -x)) = qx^{-\alpha}$$
(3.3)

for x > 0, where $\alpha \in (0, 1)$, 0 and <math>p + q = 1. Then

$$\sum_{i=2}^{\lfloor n \cdot \rfloor} f(\sum_{j=1}^{i-1} X_{n,j}) X_{n,i} \Rightarrow \int_0^{\cdot} f(Z_{\alpha}(s-)) dZ_{\alpha}(s), \qquad (3.4)$$

in $\mathbb{D}[0,1]$, where $Z_{\alpha}(s)$ is an α -stable Lévy process with Lévy measure ρ iff

$$n\mathbb{P}[\frac{X_1}{b_n} \in \cdot] \xrightarrow{v} \rho(\cdot) \tag{3.5}$$

ション ふゆ くち くち くち くち くち

in $M_p(E)$.

Remark 3 Condition (3.5) implies that X_i is regularly varying random variable. b_n is the the normalization factor, it is determined by the quantile of X_i .

ション ふゆ くち くち くち くち くち

Remark 4 To discuss the weak convergence of heavy-tailed random variables, X_1 is usually assumed to be symmetric, but we don't have such assumption. In order to use the martingale convergence method, we study the asymptotic properties of

$$X_{n,j} = \frac{X_j}{b_n} - \mathbb{E}(h(\frac{X_j}{b_n}))$$

instead of $\frac{X_j}{b_n}$.

Remark 5 The limiting process in Theorem 2 is stochastic integral driven by α -stable Lévy process. The main difference between this result and Theorem 1 is the continuity of the limiting process. For the heavy-tailed case, the limiting process is discontinuous. It will be more complex than the continuous case, we should modify the martingale convergence method.

Remark 6 When X_n is a stationary sequence instead of an i.i.d. sequence, we have the following theorem.

▲□▶ ▲□▶ ▲□▶ ▲□▶ = 三 のへぐ

Theorem 4 Let $f : \mathbb{R} \to \mathbb{R}$ be a continuous differentiable function satisfying (3.1), for some constants K > 0, a > 0 and all $x, y \in \mathbb{R}$. Suppose that $\{X_n\}_{n \ge 1}$ is a sequence of stationary random variables, defined on the probability space $(\Omega, \mathscr{F}, \mathbb{P})$. Set

$$X_{n,j} = \frac{X_j}{b_n} - \mathbb{E}(h(\frac{X_j}{b_n})|\mathscr{F}_{j-1})$$
(3.6)

for some $b_n \to \infty$. Define ρ as (3.3) for $\alpha \in (0, 1)$.

Then

$$\sum_{i=2}^{[n\cdot]} f(\sum_{j=1}^{i-1} X_{n,j}) X_{n,i} \Rightarrow \int_0^{\cdot} f(Z_{\alpha}(s-)) dZ_{\alpha}(s), \qquad (3.7)$$

in $\mathbb{D}[0,1]$, where $Z_{\alpha}(s)$ is an α -stable Lévy process with Lévy measure ρ if

$$\sum_{j=1}^{[nt]} \mathbb{P}[X_{n,j} > x | \mathscr{F}_{j-1}] \xrightarrow{\mathbb{P}} t\rho(x,\infty) \quad \text{if} \quad x > 0$$
(3.8)

and

$$\sum_{j=1}^{[nt]} \mathbb{P}[X_{n,j} < x | \mathscr{F}_{j-1}] \xrightarrow{\mathbb{P}} t\rho(-\infty, x) \quad \text{if} \quad x < 0.$$
(3.9)

Remark 7 The condition (3.5) is crucial for the proof of Theorem 3, it depicts the convergence of compensator jump measure. Conditions (3.8), and (3.9) also depict the the convergence of compensator jump measure respectively, so the proofs of Theorem 3 is similar based on the convergence of compensator jump measure.

We set

$$\mu_n(\omega; ds, dx) = \sum_{i=1}^n \varepsilon_{\left(\frac{i}{n}, \frac{X_i(\omega)}{b_n}\right)}(ds, dx),$$

then

$$\nu_n(\omega; ds, dx) := \sum_{i=1}^n \varepsilon_{(\frac{i}{n})}(ds) \mathbb{P}(\frac{X_i}{b_n} \in dx)$$

is the compensator of μ_n by the independence of $\{X_i\}_{i\geq 1}$. Set

$$\zeta_n(\omega; ds, dx) = \sum_{i=1}^n \varepsilon_{(\frac{i}{n}, \frac{X_i(\omega)}{b_n} - c_n)}(ds, dx),$$

we have

$$\varphi_n(\omega; ds, dx) := \sum_{i=1}^n \varepsilon_{(\frac{i}{n})}(ds) \mathbb{P}(\frac{X_i}{b_n} - c_n \in dx)$$

is the compensator of $\zeta_n(\omega; ds, dx)$, where $c_n = \mathbb{E}[h(\frac{X_1}{b_n})]$.

For $S_n(t)$,

$$S_n(t) = \int_0^t \int h(x)(\mu_n(ds, dx) - \nu_n(ds, dx)) + \sum_{i=1}^{[nt]} (\frac{X_i}{b_n} - h(\frac{X_i}{b_n}))$$

=: $\widetilde{S}_n(t) + \sum_{i=1}^{[nt]} (\frac{X_i}{b_n} - h(\frac{X_i}{b_n})).$

The predictable characteristics of $\widetilde{S}_n(t)$ are

$$B_n^2(t) = 0,$$

$$C_n^{22}(t) = \int_0^t \int h^2(x)\nu_n(ds, dx) - \sum_{s \le t} (\int h(x)\nu_n(\{s\}, dx))^2.$$

We need to prove

 $(B_n, C_n, \lambda_n) - (B \circ S_n(t), C \circ S_n(t), \lambda \circ S_n(t)) \xrightarrow{\mathbb{P}} 0$ (c.f. Theorem A), where λ_n is the compensated jump measure of \widetilde{Y}_n . It implies the tightness of \widetilde{Y}_n , which means that the subsequence of distribution of \widetilde{Y}_n weakly converges to a limit. The predictable characteristics of different limiting processes are (B, C, λ) by the Theorem A. Furthermore, since (3.1), the martingale problem $\varsigma(\sigma(Y_0), Y | \mathcal{L}_0, B, C, \lambda)$ has unique solution, $\widetilde{\mathbb{P}}$, by Theorem 6.13 in Applebaum (2009). We obtain the limiting process is unique. On the other hand, the predicable characteristics of $\int_0^{\cdot} f(Z_{\alpha}(s-)) dZ_{\alpha}(s)$ under \mathbb{P} are (B, C, λ) . We can identify the limiting process, $\int_{0}^{\cdot} f(Z_{\alpha}(s-)) dZ_{\alpha}(s)$, under \mathbb{P} .
